

Purple Fabric MSOCK — Platform Reference

Reference note compiled 10 September 2026 from the public product page at purplefabric.ai/msock. Product facts belong to Purple Fabric; the wording and organisation of this document are original. Prepared as knowledge-base content for the offline agent runtime.

1. What MSOCK is

MSOCK stands for Multidimensional-Multilayer System of Connected Knowledge. It is an enterprise knowledge infrastructure platform aimed at AI-governed operations inside regulated financial institutions. Its stated purpose is to make enterprise knowledge computationally understandable, so that AI systems can act on an accurate model of the actual estate rather than on inference or guesswork.

The distinction the product draws is between an AI that is intelligent and an AI that is accurate. Its argument is that intelligence without connected knowledge produces plausible answers that are not reliably correct, which is unacceptable in a regulated setting.

2. The problem it addresses

Purple Fabric characterises enterprise knowledge as living in silos — disconnected, incomplete and constantly changing. Context is scattered across tickets, repositories, pipelines, chats and meetings, so no single view describes how a system actually behaves.

A specific failure it calls out is the conflation of connected with affected. Teams that treat any two related components as mutually impacted either miss genuine risk or over-test defensively. MSOCK's position is that relationships must be evidence-backed rather than inferred from proximity.

3. Three defining characteristics

Multidimensional context. Every object is evaluated against business, operational and technical layers at once, rather than being described from a single viewpoint.

Accurate relationships. Connections between objects are supported by evidence, not derived from how near two things appear to be.

Living knowledge. The model updates as the underlying systems change, which is what keeps it from going stale and quietly becoming wrong.

4. The seven knowledge layers

MSOCK organises what it knows about an estate into seven layers, from what the user sees down to what the system runs on.

Layer	Covers
L1	User journeys and user interface
L2	Service interactions

L3	API contracts
L4	Service architecture
L5	Data models and databases
L6	Operations
L7	Infrastructure and deployment

5. The 21-dimension spatial graph

The visualisation layer places systems across 21 dimensions, grouped into five themes. The grouping matters more than the individual numbering: it separates what the business intends from how the estate actually executes, and isolates legacy residue in its own group.

Dimensions	Theme	Content
D1–D3	Experience and intent	Business journeys, UI flows, capability maps
D4–D7	Governance and trust	Business rules, compliance footprints, security posture, reliability maps
D8–D12	Execution and connectivity	Service interactions, call chains, API contracts, data relations, lineage
D13–D17	Infrastructure and estate	Infrastructure inventory, operations playbooks, integration topologies, estate maps
D18–D21	Archaeology and seams	As-is archaeology, migration seams, interface mappings, dead code detection

6. The five-stage cognitive engine

Understand (SOCK). Connects and organises enterprise knowledge across the seven layers.

Visualise (21D spatial graph). Renders the estate across the 21 dimensions above, spanning experience, governance, execution, infrastructure and archaeology.

Assess (Blast Radius). Calculates the impact of a proposed change, with evidence chains and confidence levels attached.

Act (four engineering machines). Executes Build, Change, Run and Modernise workflows.

Govern (Command Centre). Orchestrates the delivery lifecycle across five phases with four approval gates.

7. Blast Radius

Blast Radius computes the actual reach of a change rather than a broad assumption about it. It traces impact across customer journeys, processes, policies, services, APIs, events, data, code and tests, and returns relationship chains together with the evidence behind them and a confidence level for each. This is the mechanism that separates connected from affected.

8. The four engineering machines

Machine	What it does
Build	Launches new applications by reusing existing identity, payments and fraud capabilities
Change	Identifies what a regulatory update or new feature will impact across systems before coding starts
Run	Connects alerts to logs, deployments and code owners so incidents resolve faster
Modernise	Migrates legacy systems to modern architecture with business logic preservation verified

9. Command Centre: phases, gates and personas

The delivery lifecycle runs through five phases: Ideation, Inception, Construction, Validation and Operations. Four approval gates sit along that path — G1 at the Inception checkpoint, G2 after AI decomposition, G3 before implementation, and G4 as a pre-flight validation.

Eight personas participate in the lifecycle: Product Owner, Guild, Capability Lead, Engineer, QA, Release Manager, DevOps and Security.

10. Target users and claimed outcomes

MSOCK targets highly regulated financial institutions that want to deploy AI agents while keeping risk controlled. The outcomes it claims are zero regression risk, the elimination of blind testing, deterministic certainty in place of change uncertainty, faster incident resolution, and safer modernisation of existing systems.

These are vendor claims from a product page rather than independently measured results, and should be read as positioning rather than benchmark data.
